5 / 5 submitted

Q1. DICTIONARY

ANSWER

DICTIONARY:
-> dictionary is defined as the collection of items as key_value pairs.
-> in dictionary, instead of accessing the elements through their index, it can be searched and accessed by the respective key
-> The time complexity in dictionary is order of 1.
LIST:
-> list grows or changes in size dynamically
-> list searches element one by one.
-> the time complexity of list is order of n

-> therefore list has more time complexity than dictionary as any element can be searched easily using dictionary since it includes key-value pairs
-> whereas in list an element is to be searched using their numeric index.

Q2. DICTIONARY

ANSWER

```
contacts={}
contacts["anu"]="9876543213"
contacts["madhu"]="9653784378"
print(contacts)

output:
{"anu":"9876543213","madhu":"9653784378"}
```

Q3. SET

ANSWER

DISCARD() AND REMOVE():
-> discard() method deletes the element(x) from the set
-> if x does not exist, it does nothing.
ex: a={1,2,3,4,5}
 discard(3)
 print(a) # {1,2,4,5}
 discard(6)
 print(a) # no error occurs

-> remove() method deletes x from the set.
-> if x does not exist it crashes the program.
ex: a={1,2,2,3,4,5,6}
 remove(2)
 print(a) # error

Q4. Tuple

ANSWER

TUPLE:

EX:
t=(10,20,10,30,10,40)
print(t.count(10))
print(t.index(10))
output:
3
0
-> count method counts the number of times the element occurs
-> and the index() gives the first position

Q5. SET

ANSWER

```
UNION:
ex: a={1,2,2,3,4,4}
    b={3,4,5,6,7}
print(a|b)
output: {1,2,3,4,5,6,7}
-> here it just combines the values by automatically removing the duplicates
INTERSECTION:
ex: a={1,2,3,4,5}
    b={3,4,5,6,7}
print(a&b)
output: {3,4,5}
-> this prints the common element between the sets.
DIFFERENCE:
ex: a={1,2,3,4,5,6}
    b={2,3,4,7,8,}
print(a-b)
output: {1,5,6}
-> this prints the elements only in the first set.
```
